

How much annotation time do you get back?

New time $\approx$ lookup + (1 – cache hit rate) $\times$ your current annotation time

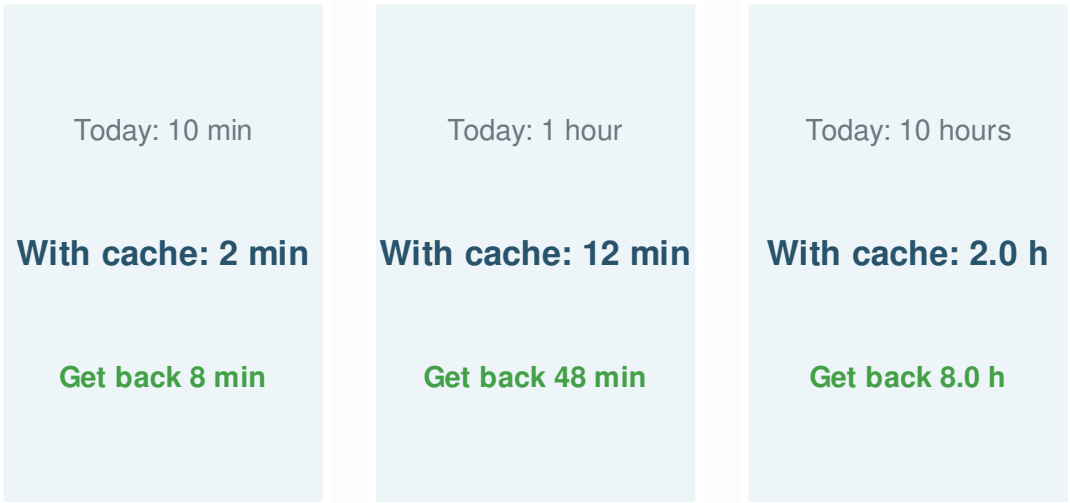

Find your expected cache reuse

Dark = annotation work left · green = waiting time returned

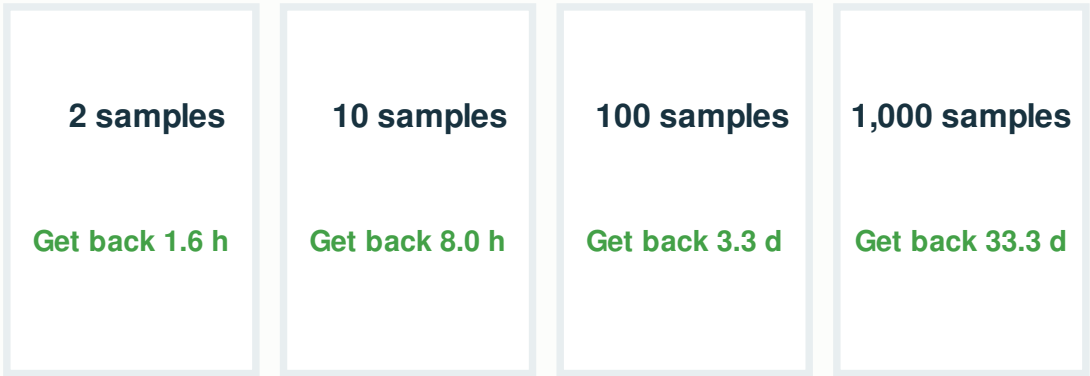

Fast or slow pipeline?

At 80% reuse, the same fraction of expensive annotation work disappears

Two samples or one thousand: savings add up

Example: 1-hour pipeline, 80% reuse, bundled cache with no build cost

✓ Same annotations

89/89 completed paired benchmark outputs pass

Any unexpected annotation change fails the task.
